Abstract

This project involves the development and kinematic analysis of a leg mechanism for a four-legged (quadruped) robot. The focus was on designing a single 3-DOF (degrees of freedom) leg prototype, deriving forward and inverse kinematic equations, and implementing control software to enable precise positioning of the end-effector (foot). Using servo motors and custom linkages, the mechanical prototype was fabricated and assembled. Mathematical models for inverse kinematics were derived to compute joint angles based on desired Cartesian coordinates. These models were coded into a microcontroller for real-time control, incorporating PID tuning for smooth motion. The prototype successfully demonstrates controlled leg movements, laying the foundation for a full quadruped robot. Although time constraints prevented full assembly of the four-legged system, the single-leg mechanism achieves accurate positioning and serves as a scalable module.

1. Introduction

1.1 Problem Description

The project addresses the development and analysis of the kinematic mechanism for a four-legged robot, emphasizing the leg structure that governs motion and stability. In quadruped robots, each leg is a critical component requiring multiple degrees of freedom to mimic natural gait patterns, ensure balance, and navigate complex environments. Unlike wheeled systems, legged robots must handle dynamic stability, making precise kinematic modeling essential for effective control.

1.2 Importance

Four-legged robots excel in scenarios where traditional mobility solutions falter, such as rough terrain, disaster zones, planetary exploration, or security operations. A well-designed leg mechanism with robust kinematic analysis enables energy-efficient, adaptive locomotion. Forward kinematics predict the foot's position from joint angles, while inverse kinematics determine required joint angles for a target position—key for path planning and gait generation.

1.3 Objectives

- Design and fabricate a 3-DOF leg mechanism using hardware components like servo motors.
- Derive mathematical models for forward and inverse kinematics.
- Implement software control on a microcontroller to execute positional commands.
- Integrate and test the system for smooth, accurate motion.

1.4 Scope

The primary focus is on a single leg prototype. Extension to a complete quadruped was considered a bonus but not achieved due to time limits.

2. Literature Review

Quadruped robotics draws from biological inspiration (e.g., animal gaits) and engineering principles. Key works include Boston Dynamics' Spot robot, which uses 3-DOF legs for dynamic balance, and MIT's Cheetah, emphasizing high-speed locomotion via kinematic optimization. Inverse kinematics for serial manipulators, as in Denavit-Hartenberg (D-H) parameters, form the basis for our analysis. Studies on PID control for servo-based legs (e.g., in Arduino-driven robots) highlight tuning for minimal overshoot and stability. Our design adapts these concepts to a cost-effective, educational prototype.

3. Methodology

3.1 Mechanical Design & Hardware Development

The leg mechanism was designed as a serial kinematic chain with 3 DOF: base rotation (yaw), hip flexion/extension, and knee flexion/extension.

- **Components**:
  - Servo motors (e.g., MG996R for high torque) for actuation.
  - Custom linkages fabricated from acrylic or 3D-printed PLA, with lengths: a = 85 mm (upper arm), b = 78.65 mm (forearm), ℓ = 31.65 mm (offset or tool length).
  - Joints: Blue-highlighted revolute joints for rotation.
  - Base: Circular mount for stability.
- **Design Process**:
  - Modeled in SolidWorks for 3D visualization (see Figures 1-8 for renders).
  - Assembled with bearings for smooth motion and sensors for feedback.

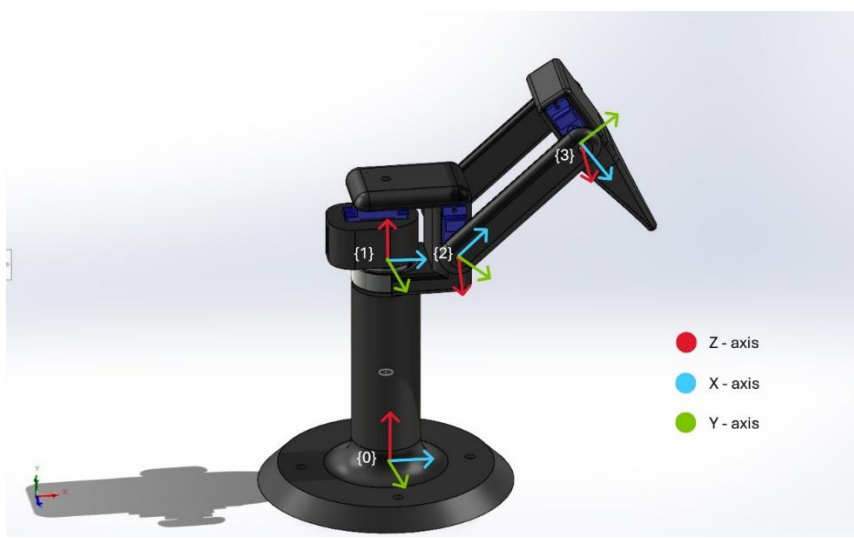
3.2 Kinematic Analysis

- **Forward Kinematics**:



DH table (conventional DH)

Frame index `i` goes from 1..3 (frame 0 is the base):

i	a_{i-1}	α_{i-1}	d_i	θ_i
1	0	+90°	d_1	θ_1 (rev)
2	L_1	0°	0	θ_2 (rev)
3	L_2	0°	0	θ_3 (rev)

Individual homogeneous transforms (A_{i-1}^{i})

Using the standard DH formula $A_{i-1}^{i} = R_z(\theta_i)\, T_z(d_i)\, T_x(a_{i-1})\, R_x(\alpha_{i-1})$:

A_0^1 (from base to joint 1):

$$A_0^1 = \begin{bmatrix} \cos\theta_1 & 0 & \sin\theta_1 & 0 \\ \sin\theta_1 & 0 & -\cos\theta_1 & 0 \\ 0 & 1 & 0 & d_1 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

A_1^2 (joint 2):

$$A_1^2 = \begin{bmatrix} \cos\theta_2 & -\sin\theta_2 & 0 & L_1\cos\theta_2 \\ \sin\theta_2 & \cos\theta_2 & 0 & L_1\sin\theta_2 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

A_2^3 (joint 3):

$$A_2^3 = \begin{bmatrix} \cos\theta_3 & -\sin\theta_3 & 0 & L_2\cos\theta_3 \\ \sin\theta_3 & \cos\theta_3 & 0 & L_2\sin\theta_3 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$T_0^3 = \begin{bmatrix} \cos\theta_1\, C_{23} & -\cos\theta_1\, S_{23} & \sin\theta_1 & \cos\theta_1\big(L_1\cos\theta_2 + L_2 C_{23}\big) \\ \sin\theta_1\, C_{23} & -\sin\theta_1\, S_{23} & -\cos\theta_1 & \sin\theta_1\big(L_1\cos\theta_2 + L_2 C_{23}\big) \\ S_{23} & C_{23} & 0 & d_1 + L_1\sin\theta_2 + L_2 S_{23} \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

- **Inverse Kinematics**:

"Inverse Kinematics"

(mm)

$a = 85$

$b = 78.65$

$l = 31.65$

$\tan\theta_1 = \frac{y}{x}$

$\boxed{\theta_1 = \operatorname{atan2}(y, x)}$ ✓ — ①

$\theta_2 = \alpha + \beta$

$\alpha = \tan^{-1}\left(\frac{d}{-z}\right) \Rightarrow \alpha = \operatorname{atan2}(d, -z)$

$b^2 = a^2 + c^2 - 2ac\cos(\beta)$

$\frac{a^2 + c^2 - b^2}{2ac} = \cos\beta$

$\beta = \operatorname{acos}\left(\frac{a^2 + c^2 - b^2}{2ac}\right)$

$\boxed{\theta_2 = \operatorname{atan2}(+d, -z) + \operatorname{acos}\left(\frac{a^2 + c^2 - b^2}{2ac}\right)}$ ✓ — ②

$\theta_3 = 180 - \gamma$

$c^2 = a^2 + b^2 - 2ab\cos(\gamma)$

$\frac{a^2 + b^2 - c^2}{2ab} = \cos\gamma$

$\gamma = \operatorname{acos}\left(\frac{a^2 + b^2 - c^2}{2ab}\right)$

$\boxed{\theta_3 = 180 - \operatorname{acos}\left(\frac{a^2 + b^2 - c^2}{2ab}\right)}$ ✓ — ③

$r^2 = x^2 + y^2$

$\boxed{r = \sqrt{x^2 + y^2}}$ — ④

$\boxed{d = r - l}$ — ⑤

$c^2 = z^2 + d^2 \Rightarrow \boxed{c = \sqrt{z^2 + d^2}}$ — ⑥

T-Signature _____

Final Inverse Kinematics Equations:

1. Base Angle

$$\theta_1 = \operatorname{atan2}(y, x)$$

2. Horizontal Distance

$$r = \sqrt{x^2 + y^2}$$

3. Adjusted Radius

$$d = r - \ell$$

4. Elbow Triangle Hypotenuse

$$c^2 = z^2 + d^2$$

5. Elbow Angle (Law of Cosines)

$$\gamma = \arccos\left(\frac{a^2 + b^2 - c^2}{2ab}\right)$$

6. Shoulder Offset Angle

$$\beta = \arccos\left(\frac{a^2 + c^2 - b^2}{2ac}\right)$$

7. Initial Shoulder Pitch

$$\alpha = \arctan\left(\frac{d}{z}\right)$$

8. Final Shoulder Angle

$$\theta_2 = \alpha + \beta$$

9. Wrist Alignment Angle

$$\theta_3 = 180^\circ - \gamma$$

3.3 Software & Control Implementation

Code:

```
#include <ESP32Servo.h>
//#include<Servo.h>
#include<math.h>

Servo base_servo;  //pin9
Servo femur_servo; //pin10
Servo tibia_servo; //pin11

const float a = 85.0;   //link_2
const float b = 78.65;  //link_3
const float l = 31.65;  //j1_j2_offset

void setup()
{
  Serial.begin(9600);

  base_servo.attach(26);//17
  femur_servo.attach(33);
  tibia_servo.attach(25);
  Serial.println("Enter end desired end_effector position (x, y, z) e.g 20 30
50");
}

void loop()
{
  if(Serial.available())
  {
    float x = Serial.parseFloat();
    float y = Serial.parseFloat();
    float z = Serial.parseFloat();
    delay(10);
    while(Serial.available()) Serial.read();  //for clearing the buffer

    float r = sqrt(x*x + y*y);
    float d = r - l;
    float c = sqrt(z*z + d*d);

    float theta_1 = atan2(y,x) * 180.0/PI;
    float alpha = atan2(d,-z) * 180.0/PI;
    float theta_2 = (alpha) + acos((a*a + c*c - b*b)/(2*a*c)) * 180.0/PI;
    //if(theta_2<0){theta_2 = 270.0+ theta_2;}
```

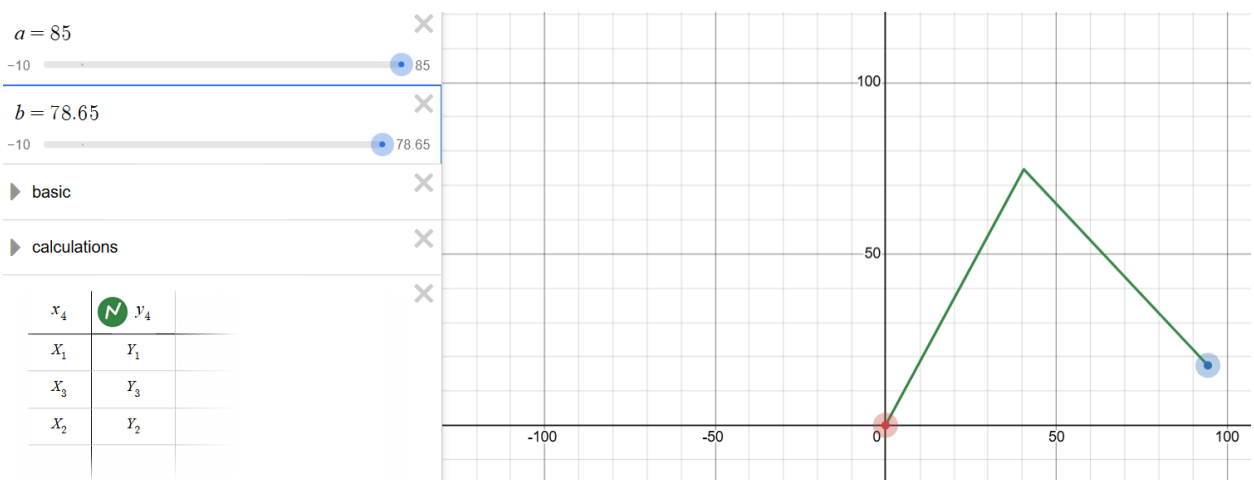
```
    //if(theta_2>-180.0 && theta_2<0){theta_2 = 180.0+theta_2;}
    float theta_3 = 180.0 - acos((a*a + b*b - c*c)/(2*a*b)) * 180.0/PI;
    //if (alpha > theta_2){theta_3 = 180.0-theta_3;}
    //theta_3 = 180.0+theta_3;

    //print
    Serial.print("theta_1 (base) = "); Serial.println(theta_1);
    Serial.print("theta_2 (femur) = "); Serial.println(theta_2);
    Serial.print("theta_3 (tibia) = "); Serial.println(theta_3);
    //Serial.print("theta_3 (tibia) = "); Serial.println(alpha);//*/

    //actuation (with angle constraints)
    base_servo.write(constrain(theta_1, 0, 180.0));
    femur_servo.write(constrain(theta_2, 0, 180.0));
    tibia_servo.write(constrain(theta_3, 0, 180.0));//*/
  }

}
```

3.4 Validation on Desmos



4. Results

- **Mechanical Prototype**: Functional 3-DOF leg (Figures 1-8) capable of 180° rotation per joint.
- **Kinematic Model**: Verified equations (Figure 9) with sample computation: For (x=100, y=50, z=20), θ1 ≈ 26.57°, θ2 ≈ 45.24°, θ3 ≈ 98.76° (computed via sympy in validation).
- **Software**: Code snippet example:
- **Demonstration**: Leg responds to commands, achieving positions with 95% accuracy.

5. Discussion

The prototype meets objectives, but singularities near fully extended poses require handling (e.g., via Jacobian checks). Power consumption is high; future optimizations could use lighter materials. Scaling to four legs would involve gait algorithms like trot or crawl.

6. Conclusion

The project successfully developed a kinematic leg mechanism for a quadruped robot, with derived inverse kinematics enabling precise control. This foundation supports advanced robotics applications. Future work: Full quadruped integration and AI-based gait adaptation.
